

A Grouping and prediction are one question at two lags

elements that always co-occur are heard as one sound;
elements that always follow are heard as a continuation

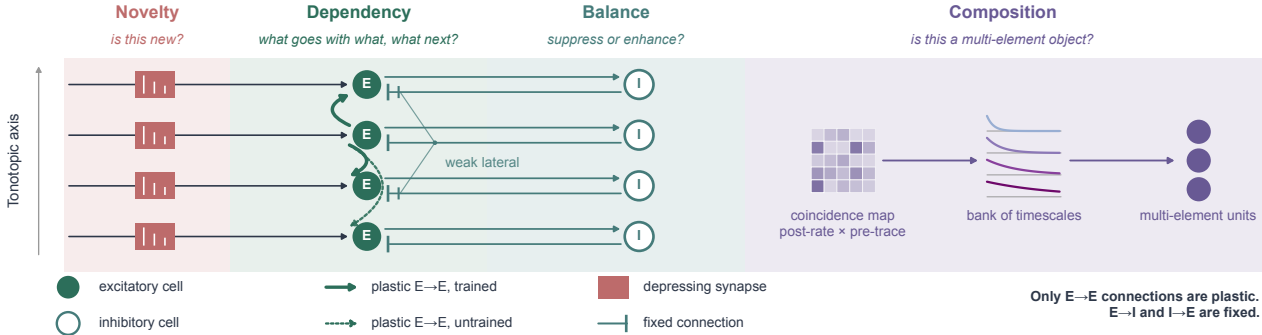

B An auditory object is a learned predictive dependency

the definition this paper works from,
in three steps and no more

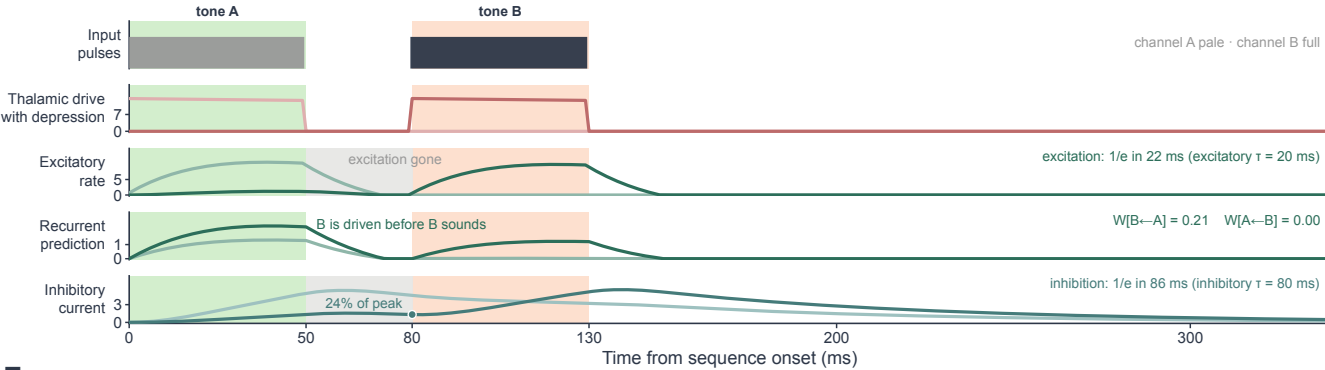

C Three memories in one cortical circuit, and a stage that reads it

depression is unlearned and channel-specific · recurrent excitation is learned and cross-channel · inhibition is fixed and slow

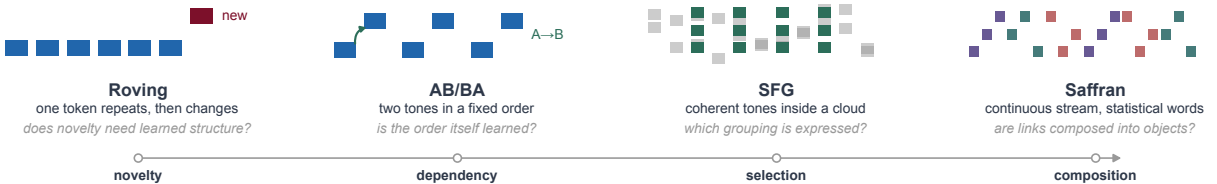

D Inhibition outlives the excitation that caused it

measured model0 output · mean of 174 AB sequences once the link is learned · no smoothing or rescaling
at tone-B onset the inhibitory current is still 24% of its peak while the excitation that drove it has returned to zero

E Four paradigms, each starting where the last one stops

depression cannot represent order · a learned link cannot choose between organisations · pairwise links are not multi-element objects

F Each paradigm is predicted to need a different subset

predictions entering the Results, not results · the synthesis figure revisits this matrix with measured effect sizes
